Introduction

Lead dislodgement is an unusual complication and a significant dangerous occurrence. Twiddler syndrome and reel syndrome, consisting of lead dislodgement caused by generator rotation on its long axis and transverse axis, respectively, have been previously reported.1-3 Ratchet syndrome is another mechanism of lead retraction, caused by ratchet-like movement of the lead through the suture sleeve.3, 4 We here report a case of ratchet syndrome caused by a small hairpin curve of the lead.

Case Report

Patient was a 69-year-old man. He had inferior wall myocardial infarction in 2000 and progressive congestive heart failure despite appropriate medical therapy. He had New York Heart Association class III heart failure, with ejection fraction of 27%. PQ interval was 281 ms (first degree atrioventricular block) and QRS durations was 131 ms. CRT-D (cardiac resynchronization therapy with an implantable cardiac defibrillator (CRTD) at our hospital. At 33 days after implantation, shock lead dislodgement was revealed. X-ray showed that the lead tip was in left subclavian vein, leaving its screw out, and a large part of the proximal portion of the lead was retracted into the pocket, while the other two leads remained in appropriate positions and the device had not rotated. An X-ray series showed that a hair-pin curve had been expanding gradually from just after implantation. In this case, relatively stiff shock lead was markedly bent and expanded the curve in the pocket, and ratchet-like movement occurred. We here report a new type of ratchet syndrome.

Abstract

There have been few reports about ratchet syndrome. We report a case of ratchet syndrome caused by small hair-pin curve of lead that triggered the lead retract itself. A 69-year-old man with a past history of inferior wall myocardial infarction, presented with progressive congestive heart failure. He underwent implantation of cardiac resynchronization therapy with an implantable cardiac defibrillator at our hospital. At 33 days after implantation, shock lead dislodgement was revealed. X-ray showed that the lead tip was in left subclavian vein, leaving its screw out, and a large part of the proximal portion of the lead was retracted into the pocket, while the other two leads remained in appropriate positions and the device had not rotated. An X-ray series showed that a hair-pin curve had been expanding gradually from just after implantation. In this case, relatively stiff shock lead was markedly bent and expanded the curve in the pocket, and ratchet-like movement occurred. We here report a new type of ratchet syndrome.

the lead, and it was successfully repositioned at the right ventricular apex. After reoperation, there were no subsequent problems. A small hair-pin curve of the shock lead in the pocket was found in the present case. Differences in the length of each lead caused the small hair-pin curve in the pocket. An X-ray series showed that the hair-pin curve had been expanding gradually from just after implantation (Fig. 3).

**Discussion**

In this case, a large part of the proximal portion of the lead was retracted into the pocket, but the generator was fixed in the pocket and had not rotated. The mechanism in this case is completely different from that of reel syndrome and twiddler syndrome. Ratchet syndrome is due to ratchet-like movement of the lead in the sleeve. When ligation of the suture sleeve is insufficient, the pendula-like movement of the generator due to movement of the arm may cause ratchet syndrome. The relatively stiff shock lead was markedly bent and could expand the hair-pin curve in the pocket (Fig. 4). It cannot be denied the possibility that the hair-pin curve became a trigger to pull the lead. Once ratchet-like movement occurred in the suture sleeve due to the hair-pin curve, the lead could slide into the pocket repeatedly. In order to avoid ratchet syndrome, it is important not only to ligate the suture sleeve firmly, but also to avoid such a small hair-pin curve. As the DF4 lead is very stiff around the connector, it may easily induce pendulum-like movement. As the atrial and left ventricular leads were strongly fixed behind the pocket, ratchet syndrome could not occur in these leads. This is a case of ratchet syndrome, not reel syndrome. We considered the other cause is the material of the lead. In previously reported cases, the material of the dislodged leads was polyurethane or silicon-polyurethane copolymer.

**Conclusion**

A small hair-pin curve may be one of the causes of ratchet syndrome.
