Abstract

Abstract: Lyme borreliosis is the most prevalent tick-borne disease in the United States (Orloski KA 2000). Lyme disease is a multisystem disorder affecting dermatologic, cardiac, nervous and musculoskeletal systems. Cardiac manifestations occur in about 5% of Lyme infections (Steere AC 1989) and stem from the involvement of the cardiac conduction system, resulting in varying degrees of sino-atrioventricular block. Occasionally, Lyme infection may also present with myopericarditis. Unlike isolated conduction node disease, myocardial involvement presents a great diagnostic and therapeutic dilemma for the physician. We report the case of a 68-year-old male cardiologist who presented with new onset exertional dyspnea and palpitations. Electrocardiograms revealed intermittent Wenckebach with markedly prolonged PR interval varying between 290-350ms. During his hospitalization, he also had a transient episode of atrial fibrillation/flutter with AV block. The patient was promptly treated with intravenous Ceftriaxone. He remained hemodynamically stable, and within 48 hours of antibiotic treatment, the patient’s arrhythmias began to resolve, and the PR interval had shortened to 230ms. He was discharged on oral Doxycycline for three weeks.

Case Report: A 68-year-old male Cardiologist, with history of Prediabetes and Benign Prostatic Hyperplasia, presented with new onset exertional dyspnea and palpitations. He reported these symptoms for one day; however, mild fatigue and general malaise had been present for approximately 6 weeks. Of note, he remained fairly active with excellent exercise tolerance until the day of presentation. The patient was an avid golfer and ran on the treadmill 5 days a week. He did not recall any tick bites, rashes or fever. Review of systems was otherwise negative. Physical examination revealed a well-nourished male who appeared his stated age. Cardiac exam revealed irregular rhythm and a variable intensity of S1. The remainder of the physical examination was unremarkable. Electrocardiograms revealed intermittent Wenckebach with markedly prolonged PR interval varying between 290-350ms (figure 1) and a transient episode of atrial fibrillation/flutter with AV block (figure 2, 3). His labs were as follows: Lyme antibodies titers IgM (3/3 bands) and IgG (5/10 bands) were positive: WBC 6.8 x 109/L, RBC 140 meq/L, Potassium 4.3 meq/L, chloride 103 meq/L, bicarbonate 28 meq/L, Calcium 9.3 mg/dL, Albumin 4.0 g/dL, T. Bilirubin 0.3 mg/dL, AST 72 units/L, ALT 150 units/L, ALP 115 units/L. On admission, his vitals were blood pressure 136/67, pulse 75, T. Bilirubin 0.3 mg/dL, AST 72 units/L, ALT 150 units/L, ALP 115 units/L. On admission, his vitals were blood pressure 136/67, pulse 75, 98% oxygen saturation on room air, temperature 98.0 F. The patient was promptly treated with intravenous Ceftriaxone. Within 36 hours of antibiotics the patients arrhythmias began to resolve. By 48 hours the patients PR interval had shortened to 230ms (figure 4). The patient remained hemodynamically stable throughout admission, and was discharged on three weeks course of oral Doxycycline.

Discussion: The degree of myopericardial involvement will largely dictate the broad array of clinical manifestations. While AV nodal disease is by far the most common manifestation, Lyme carditis may also present with SA node dysfunction, pericarditis, endocarditis, myocarditis, pericardial effusion, myocardial infarction, coronary artery aneurysm, QT interval prolongation, tachyarrhythmia’s, and congestive heart failure (Schmid GP et al 1985).

Lyme infection should be suspected in any patient who engages in high-risk activities or lives in endemic areas. Our patient, an avid golfer living in a Lyme endemic area, presented with atrial fibrillation, and complete AV block with no prior cardiac disease or risk factors.

Lyme disease with atrial fibrillation has been reported in the current literature. The etiology may be related to either SA disease or myocarditis. Management of Atrial fibrillation in the setting of Lyme carditis poses many challenges, as many of our traditional algorithms used to treat arrhythmias would be deemed unsafe. Electrical Cardioversion in the setting of an inflamed myocardium could be pro-arrhythmogenic and fatal. Pharmacological cardioversion may uncover underlying AV nodal disease caused by Lyme and induce complete heart block. For the same reasons, Class I, II, III, and IV antiarrhythmic drugs traditionally used for rate control, cannot be used in this setting. Finally anticoagulation traditionally used for stroke prevention, would be contraindicated if concomitant pericardial involvement is present for the fear of causing hemopericardium.

Antibiotics remain the mainstay of therapy. There have been no trials to compare one antibiotic from another; the data on appropriate treatment regimen comes mainly from case reports and case series. Intravenous Ceftriaxone is the drug of choice in symptomatic patients (e.g. syncope, dyspnea, or chest pain) and asymptomatic patients with marked PR prolongation (PR>300ms) (Morb Mortal Wky Rep. 2013); as the degree of block may fluctuate and rapidly worsen in such patients. Patient allergic to penicillin and its derivatives should be desensitized. IV antibiotic should be continued till the PR interval is <300ms (Wormser GP et al 2005). Asymptomatic patient should be treated with oral doxycycline, except in children <8 years old and pregnant women, where amoxicillin can be used.

The broad range of clinical manifestations often result in a delay of diagnosis or misdiagnosis. If untreated the natural history of Lyme carditis will often result in congestive heart failure and/or sudden cardiac death (Steere AC 1989). Misdiagnosis of AV dysfunction could lead to unnecessary implantation of a permanent pacemaker. Thus the treatment algorithm in Lyme induced Atrial fibrillation is different, and largely depend upon prompt diagnosis and antibiotics.
